Q: What is a good reference for understanding chemistry and the mechanisms of its reactions? What are some good references to a general understanding of the modern concepts (and thus mechanism) of chemistry, not the story of the early discovery of certain compounds, which can be a really fun read? I want something to read before I start a chemistry course, and to help me understand why a reaction is going to take place in some particular fashion. I want a book which will tell me the formula of the reactions and the structure of the compounds. I want to be able to understand what types of reactions are going on. I want something that will explain the fundamental concepts, not just share an interesting story, but give a better understanding of what's going on. If there's some book that can do this for me, then great. If there's a book that can do that and is comprehensible, and of course unvarnished, I'd love to hear about that!

A: I have a couple suggestions for you: "General Chemistry", P. G. Tait and C. Urey. "Microscopy and Microanalysis", H. G. Baker. "Spectroscopy of Inorganic Compounds", G. W. Cottrell and H. L. Miller. "Atoms in Alchemy", H. L. Miller. "Understanding Chemistry", R. K. Colton. "Introduction to Nuclear Chemistry", D. D. Street. I think that the second to last one is a good one for general chemistry, and also give a certain amount of information on reaction pathways which should make you understand the reactions. I liked the first one because it breaks down the reactions and concepts in a very nice way. It's a nice book to start with, and it shows you what you actually study in your field. And of course the last one I could give is an explanation of the formulae and reactivity of the elements.

Chauffeur Training in Suffolk Our Chauffeur Training in Suffolk offer training for novice chauffeurs. Our course offers a comprehensive introduction to key aspects of driving and offers opportunities to further build up basic driving and road safety skills. Our training is registered with the
